

Parsing

The derivation of a string produces a parse tree for the string:

Grammar:

$E \Rightarrow E+T \mid E-T \mid T$

$T \Rightarrow T * F \mid T / F \mid F$

$F \Rightarrow (E) \mid G$

$G \Rightarrow G \text{ digit} \mid \text{digit}$

Derivation:

$$\begin{aligned} E &\Rightarrow \underline{I} \\ &\Rightarrow \underline{I} * F \\ &\Rightarrow \underline{F} * F \\ &\Rightarrow \underline{G} * F \\ &\Rightarrow 3 * \underline{F} \\ &\Rightarrow 3 * (\underline{E}) \\ &\Rightarrow 3 * (\underline{E} + T) \\ &\Rightarrow 3 * (\underline{I} + T) \\ &\Rightarrow 3 * (\underline{F} + T) \\ &\Rightarrow 3 * (\underline{G} + T) \\ &\Rightarrow 3 * (4 + \underline{I}) \\ &\Rightarrow 3 * (4 + \underline{F}) \\ &\Rightarrow 3 * (4 + \underline{G}) \\ &\Rightarrow 3 * (4 + 5) \end{aligned}$$

Parse Tree:

Example 1: Find a grammar for $\{0^n 1^n \mid n \geq 0\}$ This is one of the languages we showed isn't regular.

$$S \Rightarrow 0 S 1 \mid \varepsilon$$

Example 2: Find a grammar for $\{ww^{\text{rev}} \mid w \in (0+1)^*\}$ (even-length palindromes)

$$S \Rightarrow 0 S 0 \mid 1 S 1 \mid \varepsilon$$

Example 3: Find a grammar for the language of all palindromes of 0's and 1's

$$S \Rightarrow 0 S 0 \mid 1 S 1 \mid 0 \mid 1 \mid \varepsilon$$

Note that we can reproduce the string being parsed with a left-to-right traversal of the leaves of the parse tree:

$3*(4+5)$

Regular Grammars

Consider the DFA

Here is a grammar for the language this accepts:

$$S \Rightarrow 1T \mid 0U$$
$$T \Rightarrow 0T \mid 1U$$
$$U \Rightarrow 0S \mid \varepsilon$$

$$S \Rightarrow 1T \mid 0U$$

$$T \Rightarrow 0T \mid 1U$$

$$U \Rightarrow 0S \mid \varepsilon$$

Here is a derivation of 00101:

$$S \Rightarrow 0\underline{U}$$

$$\Rightarrow 00\underline{S}$$

$$\Rightarrow 001\underline{T}$$

$$\Rightarrow 0010\underline{T}$$

$$\Rightarrow 00101\underline{U}$$

$$\Rightarrow 00101$$

Definition: A grammar that has only rules of the forms

- $X \Rightarrow a Y$
- $X \Rightarrow \varepsilon$

is called a *regular grammar*.

Theorem: The language defined by a regular grammar is regular. All regular languages are defined by regular grammars.

Proof: Given a regular grammar, build an NFA with the non-terminal symbols as states and transition function δ defined by: if $X \Rightarrow a Y$ is a grammar rule then $\delta(X, a)$ includes Y . If there is a rule $X \Rightarrow \varepsilon$ then X is a final state in the NFA. Note that every step of derivation with the grammar has the form $S \xRightarrow{*} \alpha Y$ where α is a string containing only terminal symbols. An easy induction on the length of α shows that $S \xRightarrow{*} \alpha Y$ if and only if the string α takes the automaton from its start state to state Y . This means the automaton accepts the same strings as are generated by the grammar.

On the other hand, if we start with a regular language it must have a DFA that accepts it. We can generate a regular grammar from this DFA. Again, a straightforward induction shows that the grammar defines the same language as the automaton.

Since regular grammars are context-free, we see that all regular languages are context free. But the family of context-free languages includes many languages that are not regular, including

$$\{0^n 1^n \mid n \geq 0\} \quad \{ww^{\text{rev}} \mid w \in (0+1)^*\}$$
